

Day 17 of training

Props in React

Definition:

Props (short for properties) are inputs passed from a parent component to a child component in React. They allow components to communicate and share data. Props are read-only and cannot be changed by the child component.

Key Points:

1. Props are used to pass data from parent to child.
2. Props are immutable (cannot be modified by the child).
3. Props make components reusable with different data.
4. Props can be any data type – string, number, array, object, function.
5. Props are received in the function argument (for functional components) or via `this.props` (for class components).

How to Use Props

Functional Component Example:

```
function Welcome(props) {  
  
  return <h1>Hello, {props.name}!</h1>;  
  
}
```

// Usage

```
<Welcome name="Opinder" />
```

```
<Welcome name="Alice" />
```

Output:

- Hello, Opinder!
- Hello, Alice!

Advantages of Props:

1. Enables **data flow** between components.
2. Makes components **dynamic and reusable**.
3. Promotes **modular and organized code**.
4. Helps in **event handling** through functions passed as props.
