

Day 25 – Version Control with Git and GitHub

Topics Covered:

1. Introduction to Version Control Systems (VCS)

- Learned about what a **Version Control System** is and why it's crucial in modern software development.
- Understood that version control helps track changes to code, collaborate with teams, and revert to earlier versions if necessary.
- Explored the difference between **local** version control (e.g., Git) and **remote** hosting services (e.g., GitHub, GitLab, Bitbucket).
- Discussed how Git enables developers to maintain multiple versions of a project efficiently without losing progress.

2. Installing and Configuring Git

- Downloaded and installed Git on the local system from git-scm.com.
- Verified the installation using the command:

```
bash

git --version
```

- Configured the **global username and email** to identify commits:

```
bash

git config --global user.name "Your Name"
git config --global user.email "youremail@example.com"
```

1. Updated Project Documentation

- Created and customized a **README.md** file to describe the project purpose, features, and usage.
- Added project **screenshots** to make the repository visually appealing.
- Verified that the repository appeared correctly on GitHub with all files and commit history.
